# Preliminaries

---

In this section we set up notation and terminology used in the thesis.

### 2.1 Notation and Definitions

**(Algorithms, Bitstrings and Circuits)** We define a Boolean circuit as a directed acyclic graph with input vertices and vertices implementing logical functions *and*, *or*, and *not*. We denote Boolean circuits using capital letters from the Greek and English alphabet.

We define a *probabilistic circuit* as a Boolean circuit  $C_{m,n} : \{0, 1\}^m \times \{0, 1\}^n \rightarrow \{0, 1\}^*$ . For input  $x \in \{0, 1\}^m$  we write to denote  $C_{m,n}(x; r)$  where  $r \in \{0, 1\}^n$  is called auxiliary input. If a probabilistic circuit does not take input  $x$ , we slightly abuse notation and write  $C_n(r)$ . Similarly we use  $\{C_n\}$  to denote a family of probabilist circuits that takes only auxiliary input. We make sure that it is clear from the context that probabilist circuits with only auxiliary input are not confused with circuits that do not take auxiliary input.

For a (probabilist) circuit  $C$  we write  $Size(C)$  to denote the total number of vertices of  $C$ .

We define a *two phase circuit*  $C := (C_1, C_2)$  as a circuit where in the first phase a circuit  $C_1$  is used and in the second phase a circuit  $C_2$ . If  $C_1$  and  $C_2$  are probabilistic circuits we write  $C(\delta) := (C_1, C_2)(\delta)$  to denote that in both phases  $C_1$  and  $C_2$  take as auxiliary input the same bitstring  $\delta$ .

It is well known [AB09] that a probabilistic polynomial time algorithm can be represented as a circuit of polynomial size. Moreover, it can be computed in polynomial time and logarithmic space. Therefore, whenever we state a theorem about circuits we can also apply it to polynomial time algorithms.

We write  $poly(\alpha_1, \dots, \alpha_n)$  to denote a polynomial on variables  $\alpha_1, \dots, \alpha_n$ . For an algorithm  $A$  we write  $Time(A)$  to denote the number of steps it takes to

execute  $A$ . Similarly, as for probabilistic circuits we write the randomness used by a probabilistic algorithm explicitly as a bitstring provided as an auxiliary input.

**(Probabilities and distributions)** For a finite set  $\mathcal{R}$  we write  $r \xleftarrow{\$} \mathcal{R}$  to denote that  $r$  is chosen from  $\mathcal{R}$  uniformly at random. For  $\delta \in \mathbb{R} : 0 \leq \delta \leq 1$  we write  $\mu_\delta$  to denote the Bernoulli distribution where outcome 1 occurs with probability  $\delta$  and 0 with probability  $1 - \delta$ . Moreover, we use  $\mu_\delta^k$  to denote the probability distribution over  $k$ -tuples where each element of a  $k$ -tuple is drawn independently according to  $\mu_\delta$ . Finally, let  $u \leftarrow \mu_\delta^k$  denote that a  $k$ -tuple  $u$  is chosen according to  $\mu_\delta^k$ .

Let  $(\Omega, \mathcal{F}, \Pr)$  be a probability space and  $n \in \mathbb{N}$ . We say that an event  $E_n \in \mathcal{F}$  happens *almost surely* or with *high probability* if  $\Pr[E_n] \geq 1 - 2^{-n} \text{poly}(n)$ .

**TODO:** Non-negligible function

**(Interactive protocols)** We are often interested in situations where two probabilistic algorithms interact with each other according to some protocol. We limit ourselves to the cases where algorithms interact by means of messages representable by bitstrings. A protocol execution between two probabilistic algorithms  $A$  and  $B$  is denoted by  $\langle A, B \rangle$ . The output of  $A$  in a protocol execution is denoted by  $\langle A, B \rangle_A$  and of  $B$  by  $\langle A, B \rangle_B$ . A sequence of all messages sent by  $A$  and  $B$  in the protocol execution is called a communication transcript and is denoted by  $\langle A, B \rangle_{\text{trans}}$ .

**(Oracle algorithms)**

**TODO:** set up notation

**Definition 2.1 (Polynomial time sampleable distribution)** *We say that a distribution is polynomial time sampleable if it can be approximated by polynomial time algorithm up to exponential factor.*

**Definition 2.2 (Pairwise independent family of efficient hash functions)**

*Let  $\mathcal{D}$  and  $\mathcal{R}$  be finite sets and  $\mathcal{H}$  be a family of functions mapping values from  $\mathcal{D}$  to values in  $\mathcal{R}$ . We say that  $\mathcal{H}$  is an efficient family of pairwise independent hash functions if  $\mathcal{H}$  has the following properties.*

**(Pairwise independent)** *For  $\forall x \neq y \in \mathcal{D}$  and  $\forall \alpha, \beta \in \mathcal{R}$ , it holds*

$$\Pr_{\text{hash} \leftarrow \mathcal{H}} [\text{hash}(x) = \alpha \mid \text{hash}(y) = \beta] = \frac{1}{|\mathcal{R}|}.$$

**(Polynomial time sampleable)** *For every  $\text{hash} \in \mathcal{H}$  the function  $\text{hash}$  is sampleable in time  $\text{poly}(\log |\mathcal{D}|, \log |\mathcal{R}|)$ .*

*(Efficiently computable)* For every  $hash \in \mathcal{H}$  there exists an algorithm running in time  $\text{poly}(\log |\mathcal{D}|, \log |\mathcal{R}|)$  which on input  $x \in \mathcal{D}$  outputs  $y \in \mathcal{R}$  such that  $y = hash(x)$ .

We note that the pairwise independence property is equivalent to

$$\Pr_{hash \leftarrow \mathcal{H}} [hash(x) = \alpha \wedge hash(y) = \beta] = \frac{1}{|\mathcal{R}|^2}.$$

It is well known [CW77] that there exists a family of hash functions meeting the above criteria.

## Chapter 3

---

# Weakly Verifiable Cryptographic Primitives

---

In this chapter we introduce the notion of weakly verifiable puzzles. In section 3.1 we provide a formal definitions that is followed by a series of cryptographic primitives that are captured by this notion. Finally, in Section 3.3 we give an overview of the earlier research in this area that is primarily covered in [CHS04], [DIJK09], and [HS10].

### 3.1 Weakly Verifiable Puzzles

We start by defining *dynamic weakly verifiable puzzles*.

**Definition 3.1 (Dynamic weakly verifiable puzzle.)** *A dynamic weakly verifiable puzzle (DWVP) is defined by a family of probabilistic circuits  $\{P_n\}$ . A circuit belonging to  $\{P_n\}$  is called a problem poser. A solver  $C := (C_1, C_2)$  for  $P_n$  is a probabilistic two phase circuit. We write  $P_n(\pi)$  to denote the execution of  $P_n$  with the randomness fixed to  $\pi \in \{0,1\}^n$ , and  $(C_1, C_2)(\rho)$  to denote the execution of both  $C_1$  and  $C_2$  with the randomness fixed to  $\rho \in \{0,1\}^*$ .*

*In the first phase, the problem poser  $P_n(\pi)$  and the solver  $C_1(\rho)$  interact. As the result of the interaction  $P_n(\pi)$  outputs a verification circuit  $\Gamma_V$  and a hint circuit  $\Gamma_H$ . The circuit  $C_1(\rho)$  produces no output. The circuit  $\Gamma_V$  takes as input  $q \in Q$ , an answer  $y \in \{0,1\}^*$ , and outputs a bit. We say that an answer  $(q, y)$  is a correct solution if and only if  $\Gamma_V(q, y) = 1$ . The circuit  $\Gamma_H$  on input  $q \in Q$  outputs a hint such that  $\Gamma_V(q, \Gamma_H(q)) = 1$ .*

*In the second phase,  $C_2$  takes as input  $x := \langle P_n(\pi), C_1(\rho) \rangle_{trans}$ , and has oracle access to  $\Gamma_V$  and  $\Gamma_H$ . The execution of  $C_2$  with the input  $x$  and the randomness fixed to  $\rho$  is denoted by  $C_2(x, \rho)$ . The queries of  $C_2$  to  $\Gamma_V$  and  $\Gamma_H$  are called verification queries and hint queries respectively. The circuit  $C_2$  succeeds if*

and only if it makes a verification query  $(q, y)$  such that  $\Gamma_V(q, y) = 1$ , and it has not previously asked for a hint query on  $q$ .

The above definition generalizes the previous approaches contained in [CHS04], [DIJK09], [HS10]. Some of more interesting cryptographic primitives captured by this definition are described in Section 3.2. There is no loss of generality in assuming that a problem poser and problem solver are defined by probabilistic circuits. This definition applies also when a problem poser and solver are probabilistic algorithms by using the well know fact [Hol13] that probabilistic algorithms can be represented as Boolean circuits.

## 3.2 Examples

In this section we give examples of cryptographic constructions that are dynamic weakly verifiable puzzles.

### 3.2.1 Message Authentication Codes

Let us consider the following setting. Two parties a *sender* and a *receiver* communicate over an insecure channel. Messages sent by the sender may be read and change by a third party called an *adversary*. Therefore, the receiver needs a way to ensure messages originate from the sender and are not modified. A solution is to use message authentication codes.

We assume that both the sender, receiver and adversary are polynomial time algorithms. Furthermore, the sender and the receiver share a secret key to which an adversary has no access. For each message the sender appends a tag that is computed as a function of a key and a message. For a received message the receiver compute the tag and checks whether it matches the tag appended to the message. Below we give more formal definition, based on [Mau13] and [Gol04], of message authentication codes (MAC) and MAC security.

**Definition 3.2 (Message Authentication Codes (MAC))** *Let  $\mathcal{M}$  be a set of messages,  $\mathcal{K}$  a set of keys and finally  $\mathcal{T}$  a set of tags. The message authentication code is a function  $f : \mathcal{M} \times \mathcal{K} \rightarrow \mathcal{T}$ , and it is secure if additionally satisfies the following condition:*

*Let  $k$  be chosen uniformly at random from  $\mathcal{K}$  and  $\Gamma_H : \mathcal{M} \rightarrow \mathcal{T}$  be an oracle computing a tag for the key  $k$  and a message  $m$ . We say that MAC is secure if there is not probabilistic polynomial time algorithm that with non-negligible probability outputs a message  $m'$ , as well as corresponding MAC  $t'$  such that  $f(m', k) = t$ .*

We show how the above definition of MAC is captured by dynamic weakly verifiable puzzles. The first phase is non interactive. The  $k$  key corresponds to a bitstring  $\pi \in \{0, 1\}^n$  taken by a problem poser  $P_n$ . The problem poser

outputs a hint circuit  $\Gamma_H : \mathcal{M} \rightarrow \mathcal{T}$  that given a message computes a tag. and a verification circuit  $\Gamma_V : \mathcal{M} \times \mathcal{T} \rightarrow \{0, 1\}$  that on input  $m \in \mathcal{M}$  and  $t \in \mathcal{T}$  outputs one if and only if  $f(m, k) = t$ .

The adversary is a probabilistic polynomial time algorithm, thus equivalently it can be turn into a circuit of polynomial size. In the second phase the adversary takes no input ( $x^*$  is empty string), but is given oracle access to  $\Gamma_H$  and  $\Gamma_V$ . The adversary succeeds in breaking the security of MAC if it finds a valid tag  $t' \in \mathcal{T}$  for a message  $m' \in \mathcal{M}$  such that a hint for this message has not been asked before. That corresponds to asking a successful verification query to oracle circuit  $\Gamma_V$ . Conversely, if there is no polynomial time algorithm that succeeds in solving this dynamic weakly verifiable puzzle with non-negligible probability then the message authentication code is secure.

Thus, a game in which an adversary has to break security of MAC is a dynamic weakly verifiable puzzle which first phase is not interactive, as the adversary does not communicate with the problem poser.

### 3.2.2 Public Key Signature Scheme

First we give a definition of public key encryption scheme and security of such a scheme. Both definition are based on [Gol04].

**Definition 3.3 (Public key signature scheme)** *A public key encryption scheme is defined by a triple of probabilistic polynomial time algorithms:  $G$  the key generation algorithm,  $V$  the verification algorithm,  $S$  the verification algorithm such that the following conditions are satisfied:*

*$G(1^n)$  outputs a pair of bitstrings  $k_{priv}$  a private key,  $k_{pub}$  a public key.*

*For every  $k_{priv}$ ,  $k_{pub}$  output by  $G$  and  $q \in Q$  it holds*

$$\Pr[V(k_{pub}, q, S(k_{priv}, q))] = 1.$$

**Definition 3.4 (Security of public key signature scheme with respect to the chosen message attack)** *Let us consider a situation in which an adversary is given a public key  $k_{pub}$  and can ask for a signature of chosen messages. We say that the adversary succeeds if it finds a valid signature for a message for which a signature has not been asked. Furthermore, we say that the public key encryption scheme is secure if probability that any polynomial time bounded adversary succeeds in breaking the signature scheme with negligible probability.*

We show now that the public key signature schemes are also captured by definition 3.1. First the problem poser uses algorithm  $G(1^n)$  to obtain a public and private key. Then it generates a hint circuit  $\Gamma_H : \mathcal{M} \rightarrow \mathcal{S}$  and a verification circuit  $\Gamma_V : \mathcal{M} \times \mathcal{S} \rightarrow \{0, 1\}$ . The hint circuit takes as input  $m \in$

$\mathcal{M}$  and outputs a signature for  $m$ . The verification circuit checks whether signature  $s \in S$  is a valid for message  $m \in \mathcal{M}$ . In the second phase the problem solver obtains  $k_{pub}$ , and is given oracle access to the hint circuit and verification circuit. The problem solver can ask a hint oracle for signature on chosen message.

Finally, it is clear that if a problem solver succeeds in solving a DWVP defined as above, it also breaks the security of the public signature schemes.

Public key signature schemes are type of puzzles that are dynamic - the problem poser gain oracle access to hint and verification circuits, but are not interactive.

# Security amplification for dynamic weakly verifiable puzzles

---

In this chapter we show that it is possible to amplify security of dynamic weakly verifiable puzzles. In section 4.1 we state the theorem, which is next proved in three steps. First, in Section 4.1.3, we show how to use to partition the domain on which hint and verification queries are asked, next we give a prove of security amplification under the simplifying assumption that there is no collisions of hint and verification queries. Finally, in Section 4.1.5 we combine both former steps which yields the desirable result.

### 4.1 Main theorem

We start by giving the definition of the  $k$ -wise direct product of weakly verifiable puzzles.

#### 4.1.1 The $k$ -wise direct product of weakly verifiable puzzle

**Definition 4.1 ( $k$ -wise direct-product of DWVPs.)** Let  $g : \{0, 1\}^k \rightarrow \{0, 1\}$  be a monotone function and  $P_n^{(1)}$  a problem poser as in Definition 3.1. The  $k$ -wise direct product of  $P_n^{(1)}$  is a DWVP defined by a circuit  $P_{kn}^{(g)}$ . We write  $P_{kn}^{(g)}(\pi^{(k)})$  to denote the execution of  $P_{kn}^{(g)}$  with the randomness fixed to  $\pi^{(k)} := (\pi_1, \dots, \pi_k)$  where for each  $1 \leq i \leq k : \pi_i \in \{0, 1\}^n$ . Let  $(C_1, C_2)(\rho)$  be a solver for  $P_{kn}^{(g)}$  as in Definition 3.1. In the first phase, the algorithm  $C_1(\rho)$  sequentially interacts in  $k$  rounds with  $P_{kn}^{(g)}(\pi^{(k)})$ . In the  $i$ -th round  $C_1(\rho)$  interacts with  $P_n^{(1)}(\pi_i)$ , and as the result  $P_n^{(1)}(\pi_i)$  generates circuits  $\Gamma_V^i, \Gamma_H^i$ . Finally, after  $k$  rounds  $P_{kn}^{(g)}(\pi^{(k)})$  outputs a verification circuit

$$\Gamma_V^{(g)}(q, y_1, \dots, y_k) := g(\Gamma_V^1(q, y_1), \dots, \Gamma_V^k(q, y_k))$$

and a hint circuit

$$\Gamma_H^{(k)}(q) := (\Gamma_H^1(q), \dots, \Gamma_H^k(q)).$$

If it is clear from the context, we omit the subscript  $n$  and write  $P(\pi)$  instead of  $P_n(\pi)$  where  $\pi \in \{0, 1\}^n$ .

A verification query  $(q, y)$  of a solver  $C$  for which a hint query on this  $q$  has been asked before cannot be a verification query for which  $C$  succeeds. Therefore, without loss of generality, we make the assumption that  $C$  does not ask verification queries on  $q$  for which a hint query has been asked before. Furthermore, we assume that once  $C$  asked a verification query that succeeds, it does not ask any further hint or verification queries.

**Experiment**  $Success^{P,C}(\pi, \rho)$

**Oracle:** A problem poser  $P$ , a solver  $C = (C_1, C_2)$  for  $P$ .

**Input:** Bitstrings  $\pi \in \{0, 1\}^n$ ,  $\rho \in \{0, 1\}^*$ .

**Output:** A bit  $b \in \{0, 1\}$ .

```

run  $\langle P(\pi), C_1(\rho) \rangle$ 
       $(\Gamma_V, \Gamma_H) := \langle P(\pi), C_1(\rho) \rangle_P$ 
       $x := \langle P(\pi), C_1(\rho) \rangle_{trans}$ 

run  $C_2^{\Gamma_V, \Gamma_H}(x, \rho)$ 
      if  $C_2^{\Gamma_V, \Gamma_H}(x, \rho)$  asks a verification query  $(q, y)$  s.t.  $\Gamma_V(q, y) = 1$  then
        return 1
return 0
    
```

We define the *success probability* of  $C$  in solving a puzzle defined by  $P$  as

$$\Pr_{\pi, \rho}[Success^{P,C}(\pi, \rho) = 1]. \quad (4.1)$$

Furthermore, we say that  $C$  *succeeds* for  $\pi, \rho$  if  $Success^{P,C}(\pi, \rho) = 1$ .

**Theorem 4.2 (Security amplification for dynamic weakly verifiable puzzles.)**

Let  $P_n^{(1)}$  be a fixed problem poser as in Definition 3.1 and  $P_{kn}^{(g)}$  a problem poser for the  $k$ -wise direct product of  $P_n^{(1)}$ . Additionally, let  $C$  be a problem solver for  $P_{kn}^{(g)}$  asking at most  $h$  hint queries and  $v$  verification queries. There exists a probabilistic algorithm  $Gen$  with oracle access to a solver circuit  $C$ , a monotone function  $g : \{0, 1\}^k \rightarrow \{0, 1\}$  and problem posers  $P_n^{(1)}, P_{kn}^{(g)}$ . Furthermore,  $Gen$  takes as input parameters  $\varepsilon, \delta, n, k, h, v$ , and outputs a solver circuit  $D$

for  $P_n^{(1)}$  such that the following holds:  
If  $C$  is such that

$$\Pr_{\substack{\pi^{(k)} \in \{0,1\}^{kn} \\ \rho \in \{0,1\}^*}} \left[ \text{Success}^{P_{kn}^{(g)}, C}(\pi^{(k)}, \rho) = 1 \right] \geq 16(h + v) \left( \Pr_{u \leftarrow \mu_\delta^k} [g(u) = 1] + \varepsilon \right)$$

then  $D$  is a two phase probabilistic circuit and satisfies almost surely

$$\Pr_{\substack{\pi \in \{0,1\}^n \\ \rho \in \{0,1\}^*}} \left[ \text{Success}^{P_n^{(1)}, D}(\pi, \rho) = 1 \right] \geq \delta + \frac{\varepsilon}{6k}.$$

Additionally,  $D$  requires oracle access to  $g$ ,  $P_n^{(1)}$ ,  $C$ , hint and verification circuits and asks at most  $\frac{6k}{\varepsilon} \log \left( \frac{6k}{\varepsilon} \right) h$  hint queries and one verification query. Finally,  $\text{Time}(\text{Gen}) = \text{poly}(k, \frac{1}{\varepsilon}, n, v, h)$  with oracle access to  $C$ .

#### 4.1.2 Intuition

**TODO:** add intuition for hashing

The idea of the algorithm  $\text{Gen}$  is to output a circuit  $D$  that solves the input puzzle often. We know that  $C$  has high success probability in solving the  $k$ -wise direct product of  $P^{(1)}$ . The algorithm  $\text{Gen}$  tries to find a puzzle such that when  $C$  runs with this puzzle fixed on the first position and disregards whether this puzzle is correctly solved then the assumptions of Theorem 4.2 are true for the  $(k - 1)$ -wise direct product. If it was possible to find such a puzzle, then  $\text{Gen}$  could recurse and solve a smaller problem. In the optimistic case we can reach  $k = 1$ , which means that we found a good circuit for solving a single puzzle by just fixing the initial puzzles of  $C$ .

Otherwise, when the first position is disregarded then the success probability of  $C$  is not substantially better. This is remarkable, as we know that  $C$  performs good for the  $k$ -wise direct product. It means that the first position is important, in the sense that  $C$  solves the puzzle on that position unusually often. Therefore, it is reasonable to construct the circuit  $D$  using  $C$  by placing the input puzzle of  $D$  on that position, and then finding remaining  $k - 1$  puzzles. The  $(k - 1)$  remaining puzzles are generated by the circuit  $D$ , hence it is possible to check whether they are correctly solved by the circuit  $C$ . We know that circuit  $C$  has good success probability, and the puzzle on the first position is important. Therefore, if we are able to find a  $(k - 1)$  puzzles such that the fact whether the  $k$ -wise direct product is correctly solved depends on whether the puzzle on the first position is correctly solved then we can assume that  $C$  is often correct on this first position.

There are some problems with this approach, first we have to ensure that we can make a decision when the algorithm  $\text{Gen}$  should recurse and when not

correctly with high probability. Then, we have to show that it is possible to find a puzzles such that  $C$  is often correct on the first position. Finally, we also have to be sure that we do not ask a hint query, on the final verification query to the oracle. To satisfy the last requirement we split the set  $Q$ .

### 4.1.3 Domain partitioning

Let  $hash : Q \rightarrow \{0, 1, \dots, 2(h + v) - 1\}$ , the idea is to partition  $Q$  such that the set of preimages of 0 for  $hash$  contains  $q \in Q$  on which  $C$  is not allowed to ask hint queries, and the first successful verification query  $(q, y)$  of  $C$  is such that  $hash(q) = 0$ . Therefore, if  $C$  makes a verification query  $(q, y)$  such that  $hash(q) = 0$ , then we know that no hint query is ever asked on this  $q$ .

We denote the  $i$ -th query of  $C$  by  $q_i$  if it is a hint query, and by  $(q_i, y_i)$  if it is a verification query. We define the following experiment *CanonicalSuccess* in which the set  $Q$  is partitioned using a function  $hash$ . We say that a solver circuit *succeeds* in the experiment *CanonicalSuccess* if it asks a successful verification query  $(q_j, y_j)$  such that  $hash(q_j) = 0$ , and no hint query  $q_i$  is asked before  $(q_j, y_j)$  such that  $hash(q_i) = 0$ .

---

**Experiment** *CanonicalSuccess* <sup>$P, C, hash$</sup> ( $\pi, \rho$ )

---

**Oracle:** A problem poser  $P$ , a solver circuit  $C = (C_1, C_2)$  for  $P$ ,  
a function  $hash : Q \rightarrow \{0, \dots, 2(h + v) - 1\}$ .

**Input:** Bitstrings  $\pi \in \{0, 1\}^n$ ,  $\rho \in \{0, 1\}^*$ .

**Output:** A bit  $b \in \{0, 1\}$ .

---

```

run  $\langle P(\pi), C_1(\rho) \rangle$ 
       $(\Gamma_V, \Gamma_H) := \langle P(\pi), C_1(\rho) \rangle_P$ 
       $x := \langle P(\pi), C_1(\rho) \rangle_{trans}$ 

run  $C_2^{\Gamma_V, \Gamma_H}(x, \rho)$ 
      if  $C_2^{\Gamma_V, \Gamma_H}(x, \rho)$  does not succeed for any verification query then
        return 0
      Let  $(q_j, y_j)$  be the first verification query such that  $\Gamma_V(q_j, y_j) = 1$ .

if  $(\forall i < j : hash(q_i) \neq 0)$  and  $(hash(q_j) = 0)$  then
  return 1
else
  return 0

```

---

We define the *canonical success probability* of a solver circuit  $C$  for  $P$  with

respect to a function *hash* as

$$\Pr_{\pi, \rho}[CanonicalSuccess^{P, C, hash}(\pi, \rho) = 1]. \quad (4.2)$$

For fixed *hash* and *P* a *canonical success* of *C* for bistrings  $\pi, \rho$  is a situation where  $CanonicalSuccess^{P, C, hash}(\pi, \rho) = 1$ .

We show that if a solver circuit *C* for *P* often succeeds in the experiment *Success*, then there exists a function *hash* such that *C* also often succeeds in the experiment *CanonicalSuccess*.

**Lemma 4.3** (*Success probability in solving DWVP with respect to a function hash.*) *For fixed  $P_n$  let  $C$  be a solver for  $P_n$  with success probability at least  $\gamma$ , asking at most  $h$  hint queries and  $v$  verification queries. Let  $\mathcal{H}$  be an efficient family of pairwise independent hash functions  $Q \rightarrow \{0, 1, \dots, 2(h + v) - 1\}$ . There exists a probabilistic algorithm *FindHash* that takes as input parameters  $\gamma, n, h, v$ , and has oracle access to  $C$  and  $P_n$ . Furthermore, *FindHash* runs in time  $\text{poly}(h, v, \frac{1}{\gamma}, n)$ , and with high probability outputs a function  $hash \in \mathcal{H}$  such that the canonical success probability of  $C$  with respect to  $hash$  is at least  $\frac{\gamma}{16(h+v)}$ .*

**Proof (4.3).** We fix a problem poser *P* and a solver *C* for *P* in the whole proof of Lemma 4.3. For  $k, l \in \{1, \dots, (h+v)\}$  and  $\alpha, \beta \in \{0, 1, \dots, 2(h+v)-1\}$  by the pairwise independence property, we have

$$\begin{aligned} \forall q_k \neq q_l \in Q : \Pr_{hash \leftarrow \mathcal{H}}[hash(q_k) = \alpha \mid hash(q_l) = \beta] &= \Pr_{hash \leftarrow \mathcal{H}}[hash(q_k) = \alpha] \\ &= \frac{1}{2(h+v)}. \end{aligned} \quad (4.3)$$

We write  $\mathcal{P}_{Success}$  to denote a set containing all  $(\pi, \rho)$  for which  $Success^{P, C}(\pi, \rho) = 1$ . Let us fix  $(\pi^*, \rho^*) \in \mathcal{P}_{Success}$ . We are interested in the probability over a choice of function *hash* of the event  $CanonicalSuccess^{P, C, hash}(\pi^*, \rho^*) = 1$ . Let

$(q_j, y_j)$  denote the first query such that  $\Gamma_V(q_j, y_j) = 1$ . We have

$$\begin{aligned}
 & \Pr_{hash \leftarrow \mathcal{H}} \left[ \text{CanonicalSuccess}^{P,C,hash}(\pi^*, \rho^*) = 1 \right] \\
 &= \Pr_{hash \leftarrow \mathcal{H}} [hash(q_j) = 0 \wedge (\forall i < j : hash(q_i) \neq 0)] \\
 &= \Pr_{hash \leftarrow \mathcal{H}} [\forall i < j : hash(q_i) \neq 0 \mid hash(q_j) = 0] \Pr_{hash \leftarrow \mathcal{H}} [hash(q_j) = 0] \\
 &\stackrel{(4.3)}{=} \frac{1}{2(h+v)} \left( 1 - \Pr_{hash \leftarrow \mathcal{H}} [\exists i < j : hash(q_i) = 0 \mid hash(q_j) = 0] \right) \\
 &\stackrel{(*)}{\geq} \frac{1}{2(h+v)} \left( 1 - \sum_{i < j} \Pr_{hash \leftarrow \mathcal{H}} [hash(q_i) = 0 \mid hash(q_j) = 0] \right) \\
 &\stackrel{(4.3)}{=} \frac{1}{2(h+v)} \left( 1 - \sum_{i < j} \Pr_{hash \leftarrow \mathcal{H}} [hash(q_i) = 0] \right) \\
 &\stackrel{(4.3)}{\geq} \frac{1}{4(h+v)}, \tag{4.4}
 \end{aligned}$$

where in  $(*)$  we used the union bound. Let us denote the set of those  $(\pi, \rho)$  for which  $\text{CanonicalSuccess}^{P,C,hash}(\pi, \rho) = 1$  by  $\mathcal{P}_{\text{Canonical}}$ . If for  $\pi, \rho$  the circuit  $C$  succeeds canonically, then for the same  $\pi, \rho$  we also have  $\text{Success}^{P,C}(\pi, \rho) = 1$ . Hence,  $\mathcal{P}_{\text{Canonical}} \subseteq \mathcal{P}_{\text{Success}}$ , and we conclude

$$\begin{aligned}
 & \Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} \left[ \text{CanonicalSuccess}^{P,C,hash}(\pi, \rho) = 1 \right] \\
 &= \Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} \left[ \text{CanonicalSuccess}^{P,C,hash}(\pi, \rho) = 1 \mid (\pi, \rho) \in \mathcal{P}_{\text{Success}} \right] \Pr_{\pi, \rho} [(\pi, \rho) \in \mathcal{P}_{\text{Success}}] \\
 &\quad + \Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} \left[ \text{CanonicalSuccess}^{P,C,hash}(\pi, \rho) = 1 \mid (\pi, \rho) \notin \mathcal{P}_{\text{Success}} \right] \Pr_{\pi, \rho} [(\pi, \rho) \notin \mathcal{P}_{\text{Success}}] \\
 &= \Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} \left[ \text{CanonicalSuccess}^{P,C,hash}(\pi, \rho) = 1 \mid (\pi, \rho) \in \mathcal{P}_{\text{Success}} \right] \Pr_{\pi, \rho} [(\pi, \rho) \in \mathcal{P}_{\text{Success}}] \\
 &\geq \Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} \left[ \text{CanonicalSuccess}^{P,C,hash}(\pi, \rho) = 1 \mid (\pi, \rho) \in \mathcal{P}_{\text{Success}} \right] \cdot \gamma \\
 &= \mathbb{E}_{(\pi, \rho) \in \mathcal{P}_{\text{Success}}} \left[ \Pr_{hash \leftarrow \mathcal{H}} [\text{CanonicalSuccess}^{P,C,hash}(\pi, \rho) = 1] \right] \cdot \gamma \\
 &\stackrel{(4.4)}{\geq} \frac{\gamma}{4(h+v)}. \tag{4.5}
 \end{aligned}$$

---

**Algorithm** FindHash<sup>*P,C*</sup>( $\gamma, n, h, v$ )

---

**Oracle:** A problem poser  $P$ , a solver circuit  $C$  for  $P$ .

**Input:** Parameters  $\gamma, n$ . The number of hint queries  $h$  and of verification queries  $v$ .

**Output:** A function  $hash : Q \rightarrow \{0, 1, \dots, 2(h + v) - 1\}$ .

---

```

for  $i := 1$  to  $32n(h + v)^2/\gamma^2$  do:
     $hash \leftarrow \mathcal{H}$ 
     $count := 0$ 
    for  $j := 1$  to  $32n(h + v)^2/\gamma^2$  do:
         $\pi \leftarrow \{0, 1\}^n$ 
         $\rho \leftarrow \{0, 1\}^*$ 
        if  $CanonicalSuccess^{P,C,hash}(\pi, \rho) = 1$  then
             $count := count + 1$ 
    if  $count \geq \frac{\gamma}{12(h+v)} \frac{32(h+v)^2}{\gamma^2} n$  then
        return  $hash$ 
return  $\perp$ 

```

---

We show that FindHash chooses  $hash \in \mathcal{H}$  such that the canonical success probability of  $C$  with respect to  $hash$  is at least  $\frac{\gamma}{16(h+v)}$  almost surely. Let  $\mathcal{H}_{Good}$  denote a family of functions  $hash \in \mathcal{H}$  for which

$$\Pr_{\pi, \rho} \left[ CanonicalSuccess^{P,C,hash}(\pi, \rho) = 1 \right] \geq \frac{\gamma}{8(h+v)}, \quad (4.6)$$

and  $\mathcal{H}_{Bad}$  be a family of functions  $hash \in \mathcal{H}$  such that

$$\Pr_{\pi, \rho} \left[ CanonicalSuccess^{P,C,hash}(\pi, \rho) = 1 \right] \leq \frac{\gamma}{16(h+v)}. \quad (4.7)$$

Let  $N$  denote the number of iterations of the inner loop of FindHash. We consider a single iteration of the outer loop of FindHash in which  $hash$  is fixed. We define independent, identically distributed, binary random variables  $X_1, \dots, X_N$  such that

$$X_i = \begin{cases} 1 & \text{if in the } i\text{-th iteration of the inner loop } count \text{ is increased} \\ 0 & \text{otherwise.} \end{cases}$$

We now turn to the case when  $hash \in \mathcal{H}_{Bad}$  and show that it is unlikely that  $hash$  is returned by FindHash. From (4.7) it follows that  $\mathbb{E}_{\pi, \rho}[X_i] \leq \frac{\gamma}{16(h+v)}$ . Therefore, for any fixed  $hash \in \mathcal{H}_{Bad}$  using the Chernoff bound we get

$$\begin{aligned} \Pr_{\pi, \rho} \left[ \frac{1}{N} \sum_{i=1}^N X_i \geq \frac{\gamma}{12(h+v)} \right] &\leq \Pr_{\pi, \rho} \left[ \frac{1}{N} \sum_{i=1}^N X_i \geq \left(1 + \frac{1}{3}\right) \mathbb{E}[X_i] \right] \\ &\leq e^{-\frac{\gamma}{16(h+v)} N/27} \leq e^{-\frac{2}{27} \frac{(h+v)}{\gamma} n} \stackrel{(*)}{\leq} e^{-\frac{2}{27} n}, \end{aligned}$$

where in (\*) we used the trivial facts that  $h+v \geq 1$  and  $\gamma \leq 1$ . The probability that  $hash \in \mathcal{H}_{Good}$ , when picked, is not returned amounts

$$\begin{aligned} \Pr_{\pi, \rho} \left[ \frac{1}{N} \sum_{i=1}^N X_i \leq \frac{\gamma}{12(h+v)} \right] &\leq \Pr_{\pi, \rho} \left[ \frac{1}{N} \sum_{i=1}^N X_i \leq \left(1 - \frac{1}{3}\right) \mathbb{E}[X_i] \right] \\ &\leq e^{-\frac{\gamma}{8(h+v)} N/18} \leq e^{-\frac{2}{9} \frac{(h+v)}{\gamma} n} \stackrel{(*)}{\leq} e^{-\frac{2}{9} n}, \end{aligned}$$

where we once more used the Chernoff bound. We now show that the probability of picking  $hash \in \mathcal{H}_{Good}$  is at least  $\frac{\gamma}{8(h+v)}$ . To obtain a contradiction suppose that

$$\Pr_{hash \leftarrow \mathcal{H}} [hash \in \mathcal{H}_{Good}] < \frac{\gamma}{8(h+v)}. \quad (4.8)$$

From this it follows that we can bound probability of canonical success as follows

$$\begin{aligned} &\Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} [CanonicalSuccess^{P,C,hash}(\pi, \rho) = 1] \\ &= \Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} [CanonicalSuccess^{P,C,hash}(\pi, \rho) = 1 \mid hash \in \mathcal{H}_{Good}] \Pr_{hash \leftarrow \mathcal{H}} [hash \in \mathcal{H}_{Good}] \\ &\quad + \Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} [CanonicalSuccess^{P,C,hash}(\pi, \rho) = 1 \mid hash \notin \mathcal{H}_{Good}] \Pr_{hash \leftarrow \mathcal{H}} [hash \notin \mathcal{H}_{Good}] \\ &\leq \Pr_{hash \leftarrow \mathcal{H}} [hash \in \mathcal{H}_{Good}] + \Pr_{\substack{hash \leftarrow \mathcal{H} \\ \pi, \rho}} [CanonicalSuccess^{P,C,hash}(\pi, \rho) = 1 \mid hash \notin \mathcal{H}_{Good}] \\ &\stackrel{(4.6)}{<} \stackrel{(4.8)}{<} \frac{\gamma}{8(h+v)} + \frac{\gamma}{8(h+v)} = \frac{\gamma}{4(h+v)}, \end{aligned}$$

which contradicts (4.5). Therefore, we conclude that the probability of choosing a  $hash \in \mathcal{H}_{Good}$  amounts at least  $\frac{\gamma}{8(h+v)}$ .

We show that FindHash picks in one of its iteration  $hash \in \mathcal{H}_{Good}$  almost surely. Let  $K$  be the number of iterations of the outer loop of FindHash and  $Y_i$  be a random variable for the event that in the  $i$ -th iteration of the outer loop  $hash \notin \mathcal{H}_{Good}$  is picked. We use  $\Pr_{hash \leftarrow \mathcal{H}} [hash \in \mathcal{H}_{Good}] \geq \frac{\gamma}{8(h+v)}$  and  $K \leq \frac{32(h+v)^2}{\gamma^2} n$ , and conclude

$$\begin{aligned} \Pr_{hash \leftarrow \mathcal{H}} \left[ \bigcap_{1 \leq i \leq K} Y_i \right] &\leq \left( 1 - \frac{\gamma}{8(h+v)} \right)^{\frac{32(h+v)^2}{\gamma^2} n} \leq e^{-\frac{\gamma}{8(h+v)} \frac{32(h+v)^2}{\gamma^2} n} \\ &\leq e^{-\frac{4(h+v)}{\gamma} n} \leq e^{-n}. \end{aligned}$$

It is clear that running time of FindHash is  $poly(n, h, v, \gamma)$  with oracle access. This finishes the proof of Lemma 4.3.  $\square$

#### 4.1.4 Amplification proof for partitioned domain

Let  $C = (C_1, C_2)$  be a solver circuit for a dynamic weakly verifiable puzzle as in definition 3.1. We write  $C_2^{(\cdot, \cdot)}$  to emphasize that  $C_2$  does not obtain direct access to hint and verification circuits. Instead, whenever  $C_2$  ask hint or verification queries, then it is answered explicitly as in the following code excerpt of the circuit  $\tilde{C}_2$ .

**Circuit**  $\tilde{C}_2^{\Gamma_H, C_2, hash}(x, \rho)$

**Oracle:** A hint circuit  $\Gamma_H$ , a circuit  $C_2$ ,  
a function  $hash : Q \rightarrow \{0, 1, \dots, 2(h + v) - 1\}$ .

**Input:** Bitstrings  $x \in \{0, 1\}^*$ ,  $\rho \in \{0, 1\}^*$ .

**Output:** A pair  $(q, y)$ .

```

run  $C_2^{(\cdot, \cdot)}(x, \rho)$ 
  if  $C_2^{(\cdot, \cdot)}(x, \rho)$  asks a hint query on  $q$  then
    if  $hash(q) = 0$  then
      return  $\perp$ 
    else
      answer the query of  $C_2^{(\cdot, \cdot)}(x, \rho)$  using  $\Gamma_H(q)$ 

  if  $C_2^{(\cdot, \cdot)}(x, \rho)$  asks a verification query  $(q, y)$  then
    if  $hash(q) = 0$  then
      return  $(q, y)$ 
    else
      answer the verification query of  $C_2^{(\cdot, \cdot)}(x, \rho)$  with 0

return  $\perp$ 

```

Given  $C = (C_1, C_2)$  we define the circuit  $\tilde{C} = (C_1, \tilde{C}_2)$ . Every hint query  $q$  asked by  $\tilde{C}$  is such that  $hash(q) \neq 0$ . Furthermore,  $\tilde{C}$  asks no verification queries. Instead, it returns  $(q, y)$  such that  $hash(q) = 0$  or  $\perp$ .

For fixed  $\pi$ ,  $\rho$ , and  $hash$  we say that the circuit  $\tilde{C}$  *succeeds* if for  $x := \langle P(\pi), C_1(\rho) \rangle_{trans}$ ,  $(\Gamma_V, \Gamma_H) := \langle P(\pi), C_1(\rho) \rangle_P$ , we have

$$\Gamma_V(\tilde{C}_2^{\Gamma_H, C_2, hash}(x, \rho)) = 1.$$

**Lemma 4.4** *For fixed  $P$ ,  $C$ , and  $hash$  the following statement is true*

$$\Pr_{\pi, \rho}[CanonicalSuccess^{P, C, hash}(\pi, \rho) = 1] \leq \Pr_{\substack{\pi, \rho \\ x := \langle P(\pi), C_1(\rho) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P(\pi), C_1(\rho) \rangle_P}}[\Gamma_V(\tilde{C}_2^{\Gamma_H, C_2, hash}(x, \rho)) = 1]$$

**Proof.** If for fixed  $\pi$ ,  $\rho$ , and  $hash$  the circuit  $C$  succeeds canonically, then for the same  $\pi$ ,  $\rho$ , and  $hash$  also  $\tilde{C}$  succeeds. Using this observation, we conclude that

$$\begin{aligned}
 & \Pr_{\pi, \rho} \left[ CanonicalSuccess^{P, C, hash}(\pi, \rho) = 1 \right] \\
 & \leq \mathbb{E}_{\substack{\pi, \rho \\ x := \langle P(\pi), C_1(\rho) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P(\pi), C_1(\rho) \rangle_P}} [\Gamma_V(\tilde{C}_2^{\Gamma_H, C_2, hash}(x, \rho)) = 1] \\
 & = \Pr_{\substack{\pi, \rho \\ x := \langle P(\pi), C_1(\rho) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P(\pi), C_1(\rho) \rangle_P}} [\Gamma_V(\tilde{C}_2^{\Gamma_H, C_2, hash}(x, \rho)) = 1] \quad \square
 \end{aligned}$$

**Lemma 4.5 (Security amplification for dynamic weakly verifiable puzzles with respect to hash.)** Let  $g : \{0, 1\}^k \rightarrow \{0, 1\}$  be a monotone function and  $P_n^{(1)}$  a fixed problem poser as in Definition 3.1 and  $\tilde{C} := (C_1, \tilde{C}_2)$  a circuit with oracle access to a function  $hash : Q \rightarrow \{0, 1, \dots, 2(h + v - 1)\}$  and a solver circuit  $C := (C_1, C_2)$  for  $P_{kn}^{(g)}$  which asks at most  $h$  hint queries and  $v$  verification queries. There exists an algorithm  $Gen$  that takes as input parameters  $\varepsilon$ ,  $\delta$ ,  $n$ ,  $k$ , has oracle access to  $P_n^{(1)}$ ,  $\tilde{C}$ ,  $hash$ ,  $g$ , and outputs a circuit  $D := (D_1, D_2)$  such that the following holds:  
If  $\tilde{C}$  is such that

$$\Pr_{\substack{\pi^{(k)} \in \{0, 1\}^{kn}, \rho \in \{0, 1\}^* \\ x := \langle P^{(g)}(\pi^{(k)}), C_1(\rho) \rangle_{trans} \\ (\Gamma_H^{(k)}, \Gamma_V^{(g)}) := \langle P^{(g)}(\pi^{(k)}), C_1(\rho) \rangle_{P^{(g)}}}} [\Gamma_V^{(g)}(\tilde{C}_2^{\Gamma_H^{(k)}, C_2, hash}(x, \rho)) = 1] \geq \Pr_{u \leftarrow \mu_\delta^k} [g(u) = 1] + \varepsilon,$$

then  $D$  satisfies almost surely

$$\Pr_{\substack{\pi \in \{0, 1\}^n, \rho \in \{0, 1\}^* \\ x := \langle P^{(1)}(\pi), D_1^{\tilde{C}}(\rho) \rangle_{trans} \\ (\Gamma_H, \Gamma_V) := \langle P^{(1)}(\pi), D_1^{\tilde{C}}(\rho) \rangle_{P^{(1)}}}} [\Gamma_V(D_2^{P^{(1)}, \tilde{C}, hash, g, \Gamma_H}(x, \rho)) = 1] \geq \delta + \frac{\varepsilon}{6k}.$$

Furthermore,  $D$  asks at most  $\frac{6k}{\varepsilon} \log\left(\frac{6k}{\varepsilon}\right) h$  hint queries and no verification queries. Finally,  $Time(Gen) = poly(k, \frac{1}{\varepsilon}, n)$  with oracle access to  $\tilde{C}$ .

Before we give the proof of Lemma 4.5 we define additional algorithms. First, we are interested in the probability that for  $u \leftarrow \mu_\delta^k$  and a bit  $b$  we have  $g(b, u_2, \dots, u_k) = 1$ . The estimate of this probability is calculated by `EstimateFunctionProbability`.

---

**Algorithm** EstimateFunctionProbability<sup>g</sup>(b, k, ε, δ, n)

---

**Oracle:** A function  $g : \{0, 1\}^k \rightarrow \{0, 1\}$ .

**Input:** A bit  $b \in \{0, 1\}$ , parameters  $k, \varepsilon, \delta, n$ .

**Output:** An estimate  $\tilde{g}_b$  of  $\Pr_{u \leftarrow \mu_\delta^k}[g(b, u_2, \dots, u_k) = 1]$ .

---

**for**  $i := 1$  **to**  $N := \frac{64k^2}{\varepsilon^2}n$  **do:**
 $u \leftarrow \mu_\delta^k$ 
 $g_i := g(b, u_2, \dots, u_k)$ 
**return**  $\frac{1}{N} \sum_{i=1}^N g_i$ 

---

**Lemma 4.6** *The algorithm EstimateFunctionProbability<sup>g</sup>(b, k, ε, δ, n) outputs an estimate  $\tilde{g}_b$  such that  $|\tilde{g}_b - \Pr_{u \leftarrow \mu_\delta^k}[g(b, u_2, \dots, u_k) = 1]| \leq \frac{\varepsilon}{8k}$  almost surely.*

**Proof.** We fix the notation as in the algorithm EstimateFunctionProbability. Let us define independent, identically distributed binary random variables  $K_1, K_2, \dots, K_N$  such that for each  $1 \leq i \leq N$  the random variable  $K_i$  takes value  $g_i$ . We use the Chernoff bound to obtain

$$\begin{aligned} \Pr \left[ \left| \tilde{g}_b - \Pr_{u \leftarrow \mu_\delta^k}[g(b, u_2, \dots, u_k) = 1] \right| \geq \frac{\varepsilon}{8k} \right] \\ = \Pr \left[ \left| \left( \frac{1}{N} \sum_{i=1}^N K_i \right) - \mathbb{E}_{u \leftarrow \mu_\delta^k}[g(b, u_2, \dots, u_k)] \right| \geq \frac{\varepsilon}{8k} \right] \leq 2 \cdot e^{-n/3}. \square \end{aligned}$$

The algorithm EvaluatePuzzles<sup>P<sup>(1)</sup>,  $\tilde{C}$ , hash</sup>( $\pi^{(k)}, \rho, n, k$ ) evaluates which of the  $k$  puzzles of the  $k$ -wise direct product defined by  $P^{(g)}$  are solved successfully by  $\tilde{C}(\rho) := (C_1, \tilde{C}_2)(\rho)$ . To decide whether the  $i$ -th puzzle of the  $k$ -wise direct product is solved successfully we need to gain access to the verification circuit for the puzzle generated in the  $i$ -th round of the interaction between  $P^{(g)}$  and  $\tilde{C}$ . Therefore, the algorithm EvaluatePuzzles runs  $k$  times  $P^{(1)}$  to simulate the interaction with  $C_1(\rho)$  each time with a fresh random bitstring  $\pi_i \in \{0, 1\}^n$  where  $1 \leq i \leq k$ .

Let us introduce some additional notation. We denote by  $\langle P^{(1)}(\pi_i), C_1(\rho) \rangle^i$  the execution of the  $i$ -th round of the sequential interaction. We use  $\langle P^{(1)}(\pi_i), C_1(\rho) \rangle_{P^{(1)}}^i$  to denote the output of  $P^{(1)}(\pi_i)$  in the  $i$ -th round. Finally, we write  $\langle P^{(1)}(\pi_i), C_1(\rho) \rangle_{trans}^i$  to denote the transcript of communication in the  $i$ -th round. We note that the  $i$ -th round of the interaction between  $P^{(1)}$  and  $C_1$  is well defined only if all previous rounds have been executed before.

To make the notation easier in the code excerpts of circuits  $C_2$ ,  $D_2$  and EvaluatePuzzles we omit superscripts of some oracles. Exemplary, we write  $\tilde{C}_2^{\Gamma_H^{(k)}, hash}$  instead of  $\tilde{C}_2^{\Gamma_H^{(k)}, C, hash}$  where the superscript of the oracle circuit  $C$

#### 4. SECURITY AMPLIFICATION FOR DYNAMIC WEAKLY VERIFIABLE PUZZLES

is omitted. We make sure that it is clear from the context which oracles are used.

---

**Algorithm** EvaluatePuzzles $^{P^{(1)}, \tilde{C}, hash}(\pi^{(k)}, \rho, n, k)$

---

**Oracle:** A problem poser  $P^{(1)}$ , a solver circuit  $\tilde{C} = (C_1, \tilde{C}_2)$  for  $P^{(g)}$ ,  
a function  $hash : Q \rightarrow \{0, 1, \dots, 2(h + v) - 1\}$ .

**Input:** Bitstrings  $\pi^{(k)} \in \{0, 1\}^{kn}$ ,  $\rho \in \{0, 1\}^*$ , parameters  $n, k$ .

**Output:** A tuple  $(c_1, \dots, c_k) \in \{0, 1\}^k$ .

---

**for**  $i := 1$  **to**  $k$  **do:** *//simulate k rounds of interaction*

$(\Gamma_V^i, \Gamma_H^i) := \langle P^{(1)}(\pi_i), C_1(\rho) \rangle_{P^{(1)}}^i$

$x_i := \langle P^{(1)}(\pi_i), C_1(\rho) \rangle_{trans}^i$

$x := (x_1, \dots, x_k)$

$\Gamma_H^{(k)} := (\Gamma_H^1, \dots, \Gamma_H^k)$

$(q, y_1, \dots, y_k) := \tilde{C}_2^{\Gamma_H^{(k)}, hash}(x, \rho)$

**if**  $(q, y_1, \dots, y_k) = \perp$  **then**

**return**  $(0, \dots, 0)$

$(c_1, \dots, c_k) := (\Gamma_V^1(q, y_1), \dots, \Gamma_V^k(q, y_k))$

**return**  $(c_1, \dots, c_k)$

---

All puzzles used by EvaluatePuzzles are generated internally thus the algorithm has access to hint circuit, and can answer itself all queries of  $\tilde{C}_2$ .

We are interested in the success probability of  $\tilde{C}$  with the bitstring  $\pi_1$  fixed to  $\pi^*$  where the fact whether  $\tilde{C}$  succeeds in solving the first puzzle defined by  $P^{(1)}(\pi_1)$  is neglected, and instead a bit  $b$  is used. More formally, we define the surplus  $S_{\pi^*, b}$  as

$$S_{\pi^*, b} = \Pr_{\pi^{(k)}, \rho} [g(b, c_2, \dots, c_k) = 1 \mid \pi_1 = \pi^*] - \Pr_{u \leftarrow \mu_\delta^k} [g(b, u_2, \dots, u_k) = 1], \quad (4.9)$$

where  $(c_2, c_3, \dots, c_k)$  is obtained as in EvaluatePuzzles.

The algorithm EstimateSurplus returns an estimate  $\tilde{S}_{\pi^*, b}$  for  $S_{\pi^*, b}$ .

---

**Algorithm** EstimateSurplus $^{P^{(1)}, \tilde{C}, g, hash}(\pi^*, b, k, \varepsilon, \delta, n)$

---

**Oracle:** A problem poser  $P^{(1)}$ , a circuit  $\tilde{C}$  for  $P^{(g)}$ , functions

$g : \{0, 1\}^k \rightarrow \{0, 1\}$  and  $hash : Q \rightarrow \{0, 1, \dots, 2(h + v) - 1\}$ .

**Input:** A bistring  $\pi^* \in \{0, 1\}^n$ , a bit  $b \in \{0, 1\}$ , parameters  $k, \varepsilon, \delta, n$ .

**Output:** An estimate  $\tilde{S}_{\pi^*, b}$  for  $S_{\pi^*, b}$ .

---

---

```

for  $i := 1$  to  $N := \frac{64k^2}{\varepsilon^2}n$  do:
     $(\pi_2, \dots, \pi_k) \xleftarrow{\$} \{0, 1\}^{(k-1)n}$ 
     $\rho \xleftarrow{\$} \{0, 1\}^*$ 
     $(c_1, \dots, c_k) := \text{EvaluatePuzzles}^{P^{(1)}, \tilde{C}, \text{hash}}((\pi^*, \pi_2, \dots, \pi_k), \rho, n, k)$ 
     $\tilde{s}_{\pi^*, b}^i := g(b, c_2, \dots, c_k)$ 
 $\tilde{g}_b := \text{EstimateFunctionProbability}^g(b, k, \varepsilon, \delta, n)$ 
return  $\left( \frac{1}{N} \sum_{i=1}^N \tilde{s}_{\pi^*, b}^i \right) - \tilde{g}_b$ 

```

---

**Lemma 4.7** *The estimate  $\tilde{S}_{\pi^*, b}$  returned by *EstimateSurplus* differs from  $S_{\pi^*, b}$  by at most  $\frac{\varepsilon}{4k}$  almost surely.*

**Proof.** We use the union bound and similar argument as in Lemma 4.6 which yields that  $\frac{1}{N} \sum_{i=1}^N \tilde{s}_{\pi^*, b}^i$  differs from  $\mathbb{E}[g(b, c_2, \dots, c_k)]$  by at most  $\frac{\varepsilon}{8k}$  almost surely. Together, with Lemma 4.6 we conclude that the surplus estimate returned by *EstimateSurplus* differs from  $S_{\pi^*, b}$  by at most  $\frac{\varepsilon}{4k}$  almost surely.  $\square$

We define the following solver circuit  $C' = (C'_1, C'_2)$  for the  $(k-1)$ -wise direct product of  $P^{(1)}$ .

---

**Circuit**  $C'_1{}^{\tilde{C}, P^{(1)}}(\rho)$

---

**Oracle:** A solver circuit  $\tilde{C} = (C_1, \tilde{C}_2)$  for  $P^{(g)}$ , a poser  $P^{(1)}$ .

**Input:** A bitstring  $\rho \in \{0, 1\}^*$ .

**Hard-coded:** A bitstring  $\pi^* \in \{0, 1\}^n$ .

---

Simulate  $\langle P^{(1)}(\pi^*), C_1(\rho) \rangle^1$

Use  $C_1(\rho)$  for the remaining  $k-1$  rounds of interaction.

---

---

**Circuit**  $\tilde{C}_2{}^{\Gamma_H^{(k-1)}, \tilde{C}, \text{hash}}(x^{(k-1)}, \rho)$

---

**Oracle:** A hint oracle  $\Gamma_H^{(k-1)} := (\Gamma_H^2, \dots, \Gamma_H^k)$ ,  
a solver circuit  $\tilde{C} = (C_1, \tilde{C}_2)$  for  $P^{(g)}$ ,  
a function  $\text{hash} : Q \rightarrow \{0, 1, \dots, 2(h+v)-1\}$ .

**Input:** A transcript of  $k-1$  rounds of interaction

$x^{(k-1)} := (x_2, \dots, x_k) \in \{0, 1\}^*$ , a bitstring  $\rho \in \{0, 1\}^*$

**Hard-coded:** A bitstring  $\pi^* \in \{0, 1\}^n$

---

Simulate  $\langle P^{(1)}(\pi^*), C_1(\rho) \rangle^1$

$(\Gamma_H^*, \Gamma_V^*) := \langle P^{(1)}(\pi^*), C_1(\rho) \rangle_{P^{(1)}}^1$

$x^* := \langle P^{(1)}(\pi^*), C_1(\rho) \rangle_{\text{trans}}^1$

---

**Algorithm**  $\text{Gen}^{P^{(1)}, \tilde{C}, g, \text{hash}}(\varepsilon, \delta, n, k)$ 

---

**Oracle:** A poser  $P^{(1)}$ , a solver circuit  $\tilde{C}$  for  $P^{(g)}$ , functions  $g : \{0, 1\}^k \rightarrow \{0, 1\}$ ,

$\text{hash} : Q \rightarrow \{0, 1, \dots, 2(h + v) - 1\}$ .

**Input:** Parameters  $\varepsilon, \delta, n, k$ .

**Output:** A circuit  $D$ .

---

**for**  $i := 1$  **to**  $\frac{6k}{\varepsilon}n$  **do:**

$\pi^* \xleftarrow{\$} \{0, 1\}^n$

$\tilde{S}_{\pi^*, 0} := \text{EstimateSurplus}^{P^{(1)}, \tilde{C}, g, \text{hash}}(\pi^*, 0, k, \varepsilon, \delta, n)$

$\tilde{S}_{\pi^*, 1} := \text{EstimateSurplus}^{P^{(1)}, \tilde{C}, g, \text{hash}}(\pi^*, 1, k, \varepsilon, \delta, n)$

**if**  $\exists b \in \{0, 1\} : \tilde{S}_{\pi^*, b} \geq (1 - \frac{3}{4k})\varepsilon$  **then**

Let  $C'_1$  have oracle access to  $\tilde{C}$ , and have hard-coded  $\pi^*$

Let  $\tilde{C}'_2$  have oracle access to  $\tilde{C}$ , and have hard-coded  $\pi^*$ .

$\tilde{C}' := (C'_1, \tilde{C}'_2)$

$g'(b_2, \dots, b_k) := g(b, b_2, \dots, b_k)$

**return**  $\text{Gen}^{P^{(1)}, \tilde{C}', g', \text{hash}}(\varepsilon, \delta, n, k - 1)$

*// all estimates are lower than  $(1 - \frac{3}{4k})\varepsilon$*

**return**  $D^{P^{(1)}, \tilde{C}, \text{hash}, g}$

---

**Proof (Lemma 4.5).** First let us consider the case where  $k = 1$ . The function  $g : \{0, 1\} \rightarrow \{0, 1\}$  is either the identity or a constant function. If  $g$  is the identity function, then the circuit  $D$  returned by  $\text{Gen}$  directly uses  $\tilde{C}$  to find a solution. From the assumptions of Lemma 4.5 it follows that  $\tilde{C}$  succeeds with probability at least  $\delta + \varepsilon$ . Hence,  $D$  trivially satisfies the statement of Lemma 4.5. In the latter case  $g$  is a constant function, and the statement is vacuously true.

For the general case, we consider two possibilities. Either  $\text{Gen}$  in one of the iterations finds an estimate  $\tilde{S}_{\pi^*, b} \geq (1 - \frac{3}{4k})\varepsilon$  or it fails and returns the circuit  $D$ .

In the former case we define a new monotone function  $g'(b_2, \dots, b_k) := g(b, b_2, \dots, b_k)$  and a new circuit  $\tilde{C}' = (C'_1, \tilde{C}'_2)$  with oracle access to  $\tilde{C} := (C_1, \tilde{C}_2)$ . By Lemma 4.7 it follows that  $S_{\pi^*, b} \geq \tilde{S}_{\pi^*, b} - \frac{\varepsilon}{4k} \geq (1 - \frac{1}{k})\varepsilon$  almost surely. Therefore, the circuit  $\tilde{C}'$  succeeds in solving the  $(k-1)$ -wise direct product of puzzles with probability at least  $\Pr_{u \leftarrow \mu_\delta^{(k-1)}}[g'(u_1, \dots, u_{k-1})] + (1 - \frac{1}{k})\varepsilon$ . In this case  $\tilde{C}'$  satisfies the conditions of Lemma 4.5 for the  $(k-1)$ -wise direct product of puzzles. Therefore, the recursive call to  $\text{Gen}$  with access to  $g'$  and  $\tilde{C}$  returns

a circuit  $D = (D_1, D_2)$  that with high probability satisfies

$$\Pr_{\pi, \rho}[\Gamma_V(D_2^{P^{(1)}, \tilde{C}, hash, g, \Gamma_H}(x, \rho)) = 1] \geq \delta + \left(1 - \frac{1}{k}\right) \frac{\varepsilon}{6(k-1)} = \delta + \frac{\varepsilon}{6k}. \quad (4.10)$$

$x := \langle P^{(1)}(\pi), D_1^{\tilde{C}}(\rho) \rangle_{trans}$   
 $(\Gamma_H, \Gamma_V) := \langle P^{(1)}(\pi), D_1^{\tilde{C}}(\rho) \rangle_{P^{(1)}}$

The only point remaining concerns the behavior of Gen when none of the estimates is greater than  $(1 - \frac{3}{4k})\varepsilon$ . Assume that...

**TODO : Give more intuition (and the correct one with references to the equations)**

Intuitively this means that  $\tilde{C}$  does not succeed on the remaining  $k-1$  puzzles with much higher probability than an algorithm that correctly solves each puzzle with probability  $\delta$ . However, from the assumptions of Lemma 4.5 we know that on all  $k$  puzzles the success probability of  $\tilde{C}$  is higher. Therefore, it is likely that the first puzzle is correctly solved unusually often. It remains to prove that this intuition is indeed correct.

We fix the notation used in the code excerpt of the circuit  $D_2$ . We consider a single iteration of the outer loop of  $D_2$ , in which values  $\pi_2, \dots, \pi_k$  are fixed. Additionally, we write  $\pi_1$  to denote the randomness of the problem poser and define  $c_1 := \Gamma_V(q, y_1)$ , where  $\Gamma_V$  is the verification circuit generated by  $P^{(1)}(\pi_1)$  in the first phase when interacting with  $D_1(r)$ . Finally, we introduce the additional notation  $\mathcal{G}_b := \{(b_1, b_2, \dots, b_k) : g(b, b_2, \dots, b_k) = 1\}$  and  $c = (c_1, c_2, \dots, c_k)$ . Using the new notation the following holds

$$\begin{aligned} \Pr_{u \leftarrow \mu_\delta^k}[u \in \mathcal{G}_b] &= \Pr_{u \leftarrow \mu_\delta^k}[g(b, u_2, \dots, u_k) = 1] \\ \Pr_{\pi^{(k)}, \rho}[c \in \mathcal{G}_b] &= \Pr_{\pi^{(k)}, \rho}[g(b, c_2, \dots, c_k) = 1]. \end{aligned} \quad (4.11)$$

We fix the randomness  $\pi_1$  of the problem poser  $P^{(1)}$  to  $\pi^*$  and use (4.9), (4.11) to obtain

$$\begin{aligned} &\Pr_{u \leftarrow \mu_\delta^k}[u \in \mathcal{G}_1] - \Pr_{u \leftarrow \mu_\delta^k}[u \in \mathcal{G}_0] \\ &= \Pr_{\pi^{(k)}, \rho}[c \in \mathcal{G}_1 \mid \pi_1 = \pi^*] - \Pr_{\pi^{(k)}, \rho}[c \in \mathcal{G}_0 \mid \pi_1 = \pi^*] - (S_{\pi^*, 1} - S_{\pi^*, 0}) \end{aligned} \quad (4.12)$$

We know that the function  $g$  is monotone, hence it holds  $\mathcal{G}_0 \subseteq \mathcal{G}_1$ , and we write (4.12) as

$$\Pr_{u \leftarrow \mu_\delta^k}[u \in \mathcal{G}_1 \setminus \mathcal{G}_0] = \Pr_{\pi^{(k)}, \rho}[c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] - (S_{\pi^*, 1} - S_{\pi^*, 0}). \quad (4.13)$$

Still having  $\pi_1 = \pi^*$  fixed we multiply both sides of (4.13) by

$$\Pr_r[\Gamma_V(D_2(x^*, r)) = 1] / \Pr_{u \leftarrow \mu_\delta^k}[u \in \mathcal{G}_1 \setminus \mathcal{G}_0],$$

$x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans}$   
 $(\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}$

which yields

$$\begin{aligned}
 & \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1] \\
 &= \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1] \Pr_{\pi^{(k)}, \rho} [c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] \frac{1}{\Pr_{u \leftarrow \mu_\delta^k} [u \in \mathcal{G}_1 \setminus \mathcal{G}_0]} \\
 &\quad - \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1] (S_{\pi^*, 1} - S_{\pi^*, 0}) \frac{1}{\Pr_{u \leftarrow \mu_\delta^k} [u \in \mathcal{G}_1 \setminus \mathcal{G}_0]}.
 \end{aligned} \tag{4.14}$$

We analyze the first summand of (4.14). First, we have

$$\begin{aligned}
 & \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1] \\
 &= \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1 \mid D_2(x^*, r) \neq \perp] \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans}}} [D_2(x^*, r) \neq \perp] \\
 &\stackrel{(*)}{=} \Pr_{\substack{\pi^{(k)}, \rho \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans}}} [c_1 = 1 \mid c \in \mathcal{G}_1 \setminus \mathcal{G}_0, \pi_1 = \pi^*] \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans}}} [D_2(x^*, r) \neq \perp], \tag{4.15}
 \end{aligned}$$

where in  $(*)$  we use the observation that the event  $D_2(x^*, r) \neq \perp$  happens if and only if the circuit  $D_2(x^*, r)$  finds  $\pi^{(k)}$  such that  $c \in \mathcal{G}_1 \setminus \mathcal{G}_0$ . Furthermore, conditioned on  $c \in \mathcal{G}_1 \setminus \mathcal{G}_0$  we have that  $\Gamma_V(D_2(x^*, r)) = 1$  occurs if and only if  $c_1 = 1$ . Inserting (4.15) to the numerator of the first summand of (4.14) yields

$$\begin{aligned}
 & \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1] \Pr_{\pi^{(k)}, \rho} [c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] \\
 &= \Pr_{\substack{r \\ x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans}}} [D_2(x^*, r) \neq \perp] \Pr_{\pi^{(k)}, \rho} [c_1 = 1 \mid c \in \mathcal{G}_1 \setminus \mathcal{G}_0, \pi_1 = \pi^*] \Pr_{\pi^{(k)}, \rho} [c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*].
 \end{aligned} \tag{4.16}$$

We consider the following two cases. If  $\Pr_{\pi^{(k)}, \rho} [c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] \leq \frac{\varepsilon}{6k}$  then

$$\Pr_{\pi^{(k)}, \rho} [c_1 = 1 \mid c \in \mathcal{G}_1 \setminus \mathcal{G}_0, \pi_1 = \pi^*] \Pr_{\pi^{(k)}, \rho} [c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] \leq \frac{\varepsilon}{6k}. \tag{4.17}$$

When  $\Pr_{\pi^{(k)}, \rho} [c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] > \frac{\varepsilon}{6k}$  the circuit  $D_2$  outputs  $\perp$  if and only if it fails in all  $\frac{6k}{\varepsilon} \log(\frac{6k}{\varepsilon})$  iterations to find  $\pi^{(k)}$  such that  $c \in \mathcal{G}_1 \setminus \mathcal{G}_0$  which

happens with probability

$$\Pr_r[D_2(x^*, r) = \perp] \leq (1 - \frac{\varepsilon}{6k})^{\frac{6k}{\varepsilon} \log(\frac{6k}{\varepsilon})} \leq \frac{\varepsilon}{6k}. \quad (4.18)$$

$x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans}$

We conclude that in both cases by (4.17) and (4.18) we have

$$\begin{aligned} & \Pr_r[D_2(x^*, r) \neq \perp] \Pr_{\pi^{(k)}, \rho}[c_1 = 1 \mid c \in \mathcal{G}_1 \setminus \mathcal{G}_0, \pi_1 = \pi^*] \Pr_{\pi^{(k)}, \rho}[c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] \\ & \geq \Pr_{\pi^{(k)}, \rho}[c_1 = 1 \mid c \in \mathcal{G}_1 \setminus \mathcal{G}_0, \pi_1 = \pi^*] \Pr_{\pi^{(k)}, \rho}[c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] - \frac{\varepsilon}{6k} \\ & = \Pr_{\pi^{(k)}, \rho}[c_1 = 1 \wedge c \in \mathcal{G}_1 \setminus \mathcal{G}_0 \mid \pi_1 = \pi^*] - \frac{\varepsilon}{6k} \\ & = \Pr_{\pi^{(k)}, \rho}[g(c) = 1 \mid \pi_1 = \pi^*] - \Pr_{\pi^{(k)}, \rho}[c \in \mathcal{G}_0 \mid \pi_1 = \pi^*] - \frac{\varepsilon}{6k} \\ & \stackrel{(4.9)}{=} \Pr_{\pi^{(k)}, \rho}[g(c) = 1 \mid \pi_1 = \pi^*] - \Pr_{u \leftarrow \mu_\delta^{(k)}}[u \in \mathcal{G}_0] - S_{\pi^*, 0} - \frac{\varepsilon}{6k}. \end{aligned} \quad (4.19)$$

$x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans}$

We insert (4.19) to (4.14) and calculate the expected value of over  $\pi^*$  which yields

$$\begin{aligned} & \Pr_{\pi, r}[\Gamma_V(D_2(x, r)) = 1] \geq \mathbb{E}_{\pi^*} \left[ \frac{\Pr_{\pi^{(k)}, \rho}[g(c) = 1 \mid \pi_1 = \pi^*] - \Pr_{u \leftarrow \mu_\delta^{(k)}}[u \in \mathcal{G}_0] - \frac{\varepsilon}{6k}}{\Pr_{u \leftarrow \mu_\delta^{(k)}}[u \in \mathcal{G}_1 \setminus \mathcal{G}_0]} \right] \\ & \quad - \mathbb{E}_{\pi^*} \left[ \left( \Pr_r[\Gamma_V(D_2(x^*, r)) = 1] (S_{\pi^*, 1} - S_{\pi^*, 0}) + S_{\pi^*, 0} \right) \frac{1}{\Pr_{u \leftarrow \mu_\delta^{(k)}}[u \in \mathcal{G}_1 \setminus \mathcal{G}_0]} \right]. \end{aligned}$$

$x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{trans}$   
 $(\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P(1)}$

(4.20)

We show that if Gen does not recurse, then the majority of estimates is low almost surely. Let us assume that

$$\Pr_\pi \left[ \left( S_{\pi, 0} \leq (1 - \frac{1}{2k})\varepsilon \right) \wedge \left( S_{\pi, 1} \leq (1 - \frac{1}{2k})\varepsilon \right) \right] < 1 - \frac{\varepsilon}{6k}, \quad (4.21)$$

then Gen recurses almost surely, because the probability that Gen does not find  $\tilde{S}_{\pi, b} \geq (1 - \frac{3}{4k})\varepsilon$  in all of the  $\frac{6k}{\varepsilon}n$  iterations is at most

$$\left( 1 - \frac{\varepsilon}{6k} \right)^{\frac{6k}{\varepsilon}n} \leq e^{-n}$$

almost surely, where we used Lemma 4.7. Therefore, under the assumption that Gen does not recurse with high probability it holds

$$\Pr_{\pi, \rho} \left[ \left( S_{\pi, 0} \leq (1 - \frac{1}{2k})\varepsilon \right) \wedge \left( S_{\pi, 1} \leq (1 - \frac{1}{2k})\varepsilon \right) \right] \geq 1 - \frac{\varepsilon}{6k}. \quad (4.22)$$

Let us define a set

$$\mathcal{W} = \left\{ \pi : \left( S_{\pi,0} \leq \left(1 - \frac{1}{2k}\right)\varepsilon \right) \wedge \left( S_{\pi,1} \leq \left(1 - \frac{1}{2k}\right)\varepsilon \right) \right\}, \quad (4.23)$$

and use  $\overline{\mathcal{W}}$  to denote the complement of  $\mathcal{W}$ . We bound the numerator of the second summand in (4.20)

$$\begin{aligned} & \mathbb{E}_{\pi^*} [S_{\pi^*,0} + \Pr_{\substack{x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{\text{trans}} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1] (S_{\pi^*,1} - S_{\pi^*,0})] \\ &= \mathbb{E}_{\pi^*} \left[ S_{\pi^*,0} + \Pr_{\substack{x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{\text{trans}} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1] (S_{\pi^*,1} - S_{\pi^*,0}) \mid \pi^* \in \overline{\mathcal{W}} \right] \Pr_{\pi^*}[\pi^* \in \overline{\mathcal{W}}] \\ &+ \mathbb{E}_{\pi^*} \left[ S_{\pi^*,0} + \Pr_{\substack{x^* := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{\text{trans}} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x^*, r)) = 1] (S_{\pi^*,1} - S_{\pi^*,0}) \mid \pi^* \in \mathcal{W} \right] \Pr_{\pi^*}[\pi^* \in \mathcal{W}] \\ &\leq \frac{\varepsilon}{6k} + \mathbb{E}_{\pi^*} \left[ S_{\pi^*,0} + \Pr_{\substack{x := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{\text{trans}} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(r) \rangle_{P^{(1)}}}} [\Gamma_V(D_2^{\tilde{C}}(x^*, r)) = 1] \left( \left(1 - \frac{1}{2k}\right)\varepsilon - S_{\pi^*,0} \right) \mid \pi^* \in \mathcal{W} \right] \Pr_{\pi^*}[\pi^* \in \mathcal{W}] \\ &\leq \frac{\varepsilon}{6k} + \left(1 - \frac{1}{2k}\right)\varepsilon = \left(1 - \frac{1}{3k}\right)\varepsilon. \end{aligned} \quad (4.24)$$

We observe that

$$\begin{aligned} \Pr_{u \leftarrow \mu_{\delta}^k} [g(u) = 1] &= \Pr[u \in \mathcal{G}_0 \vee (u \in \mathcal{G}_1 \setminus \mathcal{G}_0 \wedge u_1 = 1)] \\ &= \Pr[u \in \mathcal{G}_0] + \delta \Pr[u \in \mathcal{G}_1 \setminus \mathcal{G}_0]. \end{aligned} \quad (4.25)$$

Finally, we insert (4.24) into (4.20) which yields

$$\Pr_{\substack{x := \langle P^{(1)}(\pi), D_1(\rho) \rangle_{\text{trans}} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi), D_1(\rho) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x, \rho)) = 1] \geq \mathbb{E}_{\pi^*} \left[ \frac{\Pr_{\pi^{(k)}, \rho} [g(c) = 1 \mid \pi_1 = \pi^*] - \Pr_{u \leftarrow \mu_{\delta}^k} [u \in \mathcal{G}_0] - \left(1 - \frac{1}{6k}\right)\varepsilon}{\Pr_{u \leftarrow \mu_{\delta}^k} [u \in \mathcal{G}_1 \setminus \mathcal{G}_0]} \right].$$

From the assumptions of Lemma 4.5 it follows that

$$\Pr_{\pi^{(k)}, \rho} [g(c) = 1] \geq \Pr_{u \leftarrow \mu_{\delta}^{(k)}} [g(u) = 1] + \varepsilon.$$

thus we get

$$\begin{aligned} \Pr_{\substack{x := \langle P^{(1)}(\pi^*), D_1(\rho) \rangle_{\text{trans}} \\ (\Gamma_V, \Gamma_H) := \langle P^{(1)}(\pi^*), D_1(\rho) \rangle_{P^{(1)}}}} [\Gamma_V(D_2(x, \rho)) = 1] &\geq \frac{\Pr_{u \leftarrow \mu_{\delta}^k} [g(u) = 1] + \varepsilon - \Pr_{u \leftarrow \mu_{\delta}^k} [u \in \mathcal{G}_0] - \left(1 - \frac{1}{6k}\right)\varepsilon}{\Pr_{u \leftarrow \mu_{\delta}^k} [u \in \mathcal{G}_1 \setminus \mathcal{G}_0]} \\ &\stackrel{(4.25)}{\geq} \frac{\varepsilon + \delta \Pr_{u \leftarrow \mu_{\delta}^k} [u \in \mathcal{G}_1 \setminus \mathcal{G}_0] - \left(1 - \frac{1}{6k}\right)\varepsilon}{\Pr_{u \leftarrow \mu_{\delta}^k} [u \in \mathcal{G}_1 \setminus \mathcal{G}_0]} \geq \delta + \frac{\varepsilon}{6k} \end{aligned} \quad (4.26)$$

Clearly, the running time of Gen is  $\text{poly}(k, \frac{1}{\varepsilon}, n)$ .  $\square$

#### 4.1.5 Putting it together

In the previous sections we have shown that it is possible to partition the domain  $Q$  such that if the number of hint and verification queries is small, then success probability of a solver for the  $k$ -wise direct product is still substantial. As shown in Lemma 4.5 we can build a circuit that returns a solution that is likely to be good. It remains to use these build blocks and prove Theorem 4.2.

**Proof (of Theorem 4.2).** Let  $\widetilde{\text{Gen}}$  be the algorithm from Theorem 4.2, and  $\widetilde{D} = (D_1, D_2)$  the corresponding solver circuit for  $P$  that is output by  $\widetilde{\text{Gen}}$  as in Theorem 4.2. They are defined on the following code excerpts.

**Circuit**  $\widetilde{D}_2^{D, P^{(1)}, \text{hash}, g, \Gamma_V, \Gamma_H}(x, \rho)$

**Oracle:** A circuit  $D := (D_1, \widetilde{D}_2)$  from Lemma 4.5, a problem poser  $P^{(1)}$ , functions  $\text{hash} : Q \rightarrow \{0, 1, \dots, 2(h+v)-1\}$ ,  $g : \{0, 1\}^k \rightarrow \{0, 1\}$  a verification oracle  $\Gamma_V$ , a hint oracle  $\Gamma_H$ .

**Input:** Bitstrings  $x \in \{0, 1\}^*$ ,  $\rho \in \{0, 1\}^*$ .

$(q, y) := D_2^{P^{(1)}, \widetilde{C}, \text{hash}, g, \Gamma_H}(x, \rho)$   
Ask verification query  $(q, y)$  to  $\Gamma_V$ .

**Algorithm**  $\widetilde{\text{Gen}}^{P^{(1)}, g, C}(n, \varepsilon, \delta, k, h, v)$

**Oracle:** A problem poser  $P^{(1)}$ , a function  $g : \{0, 1\}^k \rightarrow \{0, 1\}$ , a solver circuit  $C$  for  $P^{(g)}$ .

**Input:** Parameters  $n, \varepsilon, \delta, k, h, v$ .

**Return:** A circuit  $\widetilde{D} = (D_1, \widetilde{D}_2)$ .

$\text{hash} := \text{FindHash}((h+v)\varepsilon, n, h, v)$

Let  $\widetilde{C} := (C_1, \widetilde{C}_2)$  be as in Lemma 4.4 with oracle access to  $C$ ,  $\text{hash}$ .

$D := \text{Gen}^{P^{(1)}, \widetilde{C}, g, \text{hash}}(\varepsilon, \delta, n, k)$

**return**  $\widetilde{D} := (D_1, \widetilde{D}_2)$

We show that Theorem 4.2 follows from Lemma 4.3 and Lemma 4.5. We fix  $P^{(1)}$ ,  $g$ ,  $P^{(g)}$  in the whole proof and consider a solver circuit  $C = (C_1, C_2)$ , asking at most  $h$  hint queries and  $v$  verification queries, such that

$$\Pr_{\pi^{(k)}, \rho} \left[ \text{Success}^{P^{(g)}, C}(\pi^{(k)}, \rho) = 1 \right] \geq 16(h+v) \left( \Pr_{u \leftarrow \mu_\delta^k} [g(u) = 1] + \varepsilon \right).$$

First, we note that  $C$  meets the requirements of Lemma 4.3. Thus, the algorithm  $\widetilde{\text{Gen}}$  can call FindHash to obtain  $hash$  such that with high probability it holds

$$\Pr_{\pi^{(k)}, \rho} \left[ \text{CanonicalSuccess}^{P^{(g)}, C, hash}(\pi^{(k)}, \rho) = 1 \right] \geq \Pr_{u \leftarrow \mu_{\delta}^k} [g(u) = 1] + \varepsilon.$$

Applying Lemma 4.4 for  $C$  we obtain a circuit  $\tilde{C} = (C_1, \tilde{C}_2)$  that satisfies

$$\Pr_{\pi^{(k)}, \rho} [\Gamma_V^{(g)}(\tilde{C}_2^{\Gamma_H^{(k)}, C_2, hash}(x, \rho)) = 1] \geq \Pr_{u \leftarrow \mu_{\delta}^k} [g(u) = 1] + \varepsilon.$$

$x := \langle P^{(g)}(\pi^{(k)}), C_1(\rho) \rangle_{trans}$   
 $(\Gamma_V^{(g)}, \Gamma_H^{(k)}) := \langle P^{(g)}(\pi^{(k)}), C_1(\rho) \rangle_{P^{(g)}}$

Now, we use the algorithm Gen as in Lemma 4.5 that yields a circuit  $D = (D_1, D_2)$  which with high probability satisfies

$$\Pr_{\pi, \rho} [\Gamma_V(D_2^{P^{(1)}, \tilde{C}, hash, g, \Gamma_H}(x, \rho)) = 1] \geq (\delta + \frac{\varepsilon}{6k}). \quad (4.27)$$

$x := \langle P^{(1)}(\pi), D_1^{\tilde{C}}(\rho) \rangle_{trans}$   
 $(\Gamma_H, \Gamma_V) := \langle P^{(1)}(\pi), D_1^{\tilde{C}}(\rho) \rangle_{P^{(1)}}$

Finally,  $\widetilde{\text{Gen}}$  outputs  $\tilde{D} = (D_1, \tilde{D}_2)$  with oracle access to  $D$ ,  $P^{(1)}$ ,  $hash$ ,  $g$  such that with high probability it holds

$$\Pr_{\pi, \rho} [\text{Success}^{P^{(1)}, \tilde{D}}(\pi, \rho) = 1] \geq (\delta + \frac{\varepsilon}{6k}).$$

The running time of FindHash is  $\text{poly}(h, v, \frac{1}{\varepsilon}, n)$  with oracle calls and of Gen  $\text{poly}(k, \frac{1}{\varepsilon}, n)$  with oracle access. Thus, the overall running time of  $\widetilde{\text{Gen}}$  is  $\text{poly}(k, \frac{1}{\varepsilon}, h, v, n, t)$  with oracle access. Furthermore, the circuit  $\tilde{D}$  asks at most  $\frac{6k}{\varepsilon} \log(\frac{6k}{\varepsilon})h$  hint queries and one verification query. Finally, we have  $\text{Size}(\tilde{D}) \leq \text{Size}(C) \cdot \frac{6k}{\varepsilon}$ . This finishes the proof of Theorem 4.2.  $\square$

## 4.2 Discussion

## Appendix A

### A.1 Basic Inequalities

**Lemma A.1 (Chernoff Bounds)** *For independent, identically distributed Bernoulli random variables  $X_1, \dots, X_n$  with  $X := \sum_{i=1}^n X_i$  with  $\Pr[X_i = 1] = p_i$  and  $\Pr[X_i = 0] = 1 - p_i$  for all  $1 \leq i \leq n$ . we have the following inequalities for  $0 \leq \delta \leq 1$  and  $\mathbb{E}[X] = \sum_{i=1}^n p_i$ :*

$$\Pr[X \geq (1 + \delta)\mathbb{E}[X]] \leq e^{-\mathbb{E}[X]\delta^2/3} \quad (\text{A.1})$$

$$\Pr[X \leq (1 - \delta)\mathbb{E}[X]] \leq e^{-\mathbb{E}[X]\delta^2/2} \quad (\text{A.2})$$

$$\Pr[|X - \mathbb{E}[X]| \geq \delta\mathbb{E}[X]] \leq 2e^{-\mathbb{E}[X]\delta^2/3}. \quad (\text{A.3})$$
